Matching

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 Template matching
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Outline

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 Template matching
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Tasks of computer vision related to matching 1/3

- Given images of a scene taken by **different sensors**, bring them into registration
 - this is multimodal **image registration**
 - in medical imaging, images obtained by sensors of different types are called *modalities*
 - interfaces that use different sensors, such as images, video, sound, haptics (tactile), are also called *multimodal*
 - when data structures to be registered are different, the term **data fusion** is used
- Given images of a scene taken at **different times**, find correspondences, displacements, or changes
 - this is **motion analysis**
 - typical example: motion tracking

Tasks of computer vision related to matching 2/3

- Given images of a scene taken from **different positions**, find correspondent points to obtain 3D information about the scene
 - this is stereopsis, or simply **stereo**
 - matching provides *disparity*: shift of point between two views
 - by triangulation, disparity and baseline (distance between cameras) provide *depth*: 3D distance to point
 - generalised stereo is called *3D scene reconstruction* from multiple views

Tasks of computer vision related to matching 3/3

- Find places in image or on contour where it **matches a given pattern**
 - *template matching*: pattern is specified by template
 - *feature detection*: feature is specified by description
- Match **two contours** for object recognition, measurement, or positioning
 - this is *contour matching*
- Only the above two tasks are considered in this course

Outline

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 Template matching
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Problems with finding correspondences

- Widespread opinion in computer vision: Solving the correspondence problem is of key importance
 - opens way to solution of many other problems
 - however, hard to tackle because of numerous critical issues
- Invariance under varying imaging conditions
 - spatial (viewpoint, distance, perspective)
 - photometric (illumination, intensity)
- Sensitivity to noise, distortions, occlusion

Transformations considered in this course

- **Spatial**

- 2D shift and rotation in image plane

- **Photometric**

- intensity shift and scaling

⇒ $I' = aI + b$

- **Meaning of intensity shift and scaling**

- a : change of *direct illumination*

⇒ illumination directed at object

- b : change of *ambient light*

⇒ overall illumination of scene

⇒ lights coming from all directions

Template matching

- Compare subimage (**template**) $w(x', y')$ with an image $f(x, y)$ for all possible displacements (x, y)
 - in other words, **match** $w(x', y')$ against $f(x + x', y + y')$ for all (x, y)
- Template matching: Varying r and c , search for locations of
 - *low dissimilarity* (mismatch) between image and template, *or*
 - *high similarity* (match) between image and template

Outline

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 **Template matching**
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Sum of Square Differences (SSD)

$$SSD(x, y) = \sum \left\{ f(x + x', y + y') - w(x', y') \right\}^2$$

where for simplicity

$$\sum \text{ denotes } \sum_{\substack{(x', y') \in W \\ (x+x', y+y') \in F}}$$

- Here
 - W is set of pixel positions in template w (template coord.)
 - F is set of pixel positions in image f (image coord.)
- $SSD(x, y)$ is *not* invariant under
 - 2D rotation \Rightarrow cannot find significantly rotated pattern
 - intensity changes \Rightarrow can't cope with varying illumination

Intensity shift-corrected SSD

$$SSD_{SC}(x, y) = \sum \left\{ \left[f(x+x', y+y') - \bar{f}(x, y) \right] - \left[w(x', y') - \bar{w} \right] \right\}^2$$

- $\bar{f}(x, y)$ is average value of image in region covered by template
 - computed in each position (x, y)
 - ⇒ use running box filter
- \bar{w} is average value of template
 - computed only once
- $SSD_{SC}(x, y)$ is used to compensate for *intensity shift* due to varying illumination
 - handles changes in average level of signal
 - does not handle changes in amplitude of signal

Outline

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 **Template matching**
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Unnormalised cross-correlation (CC)

$$CC(x, y) = \sum f(x + x', y + y') \cdot w(x', y')$$

- Properties of cross-correlation and convolution already studied
- $CC(x, y)$ is formally the same as *filtering* image f with mask w
 - ⇒ our knowledge of filters is applicable: normalisation, separability, fast implementation
- $CC(x, y)$ is *not* invariant under intensity shift and scaling
- When $w > 0$ and f is large, $CC(x, y)$ is large, independently from similarity between w and f
 - ⇒ to compensate for this, *normalised* version is used

Normalised cross-correlation (NCC)

$$NCC(x, y) = \frac{1}{N_1} \sum \left[f(x + x', y + y') - \bar{f}(x, y) \right] \cdot \left[w(x', y') - \bar{w} \right],$$

where normaliser

$$N_1 = \sqrt{S_f(x, y) \cdot S_w}$$

$$S_f(x, y) = \sum \left[f(x + x', y + y') - \bar{f}(x, y) \right]^2$$

$$S_w = \sum_{(x', y') \in W} \left[w(x', y') - \bar{w} \right]^2$$

- $S_f(x, y)$ is computed in each position (x, y) , S_w only once
- $NCC(x, y)$ is invariant to any *linear intensity transformation*
 $g(x, y) = \alpha f(x, y) + \beta$

Modified normalised cross-correlation (MNCC)

$$MNCC(x, y) = \frac{1}{N_2} \sum \left[f(x+x', y+y') - \bar{f}(x, y) \right] \cdot \left[w(x', y') - \bar{w} \right],$$

where normaliser

$$N_2 = S_f(x, y) + S_w$$

- MNCC differs from NCC only in *normalisation*
- MNCC is used to avoid numerically unstable division by small number when $S_f(x, y)$ is small
 - small image variation
- Formally, MNCC is only shift-corrected
 - in practice, insensitive to scaling: $S_f(x, y) + S_w \propto S_f(x, y)$, approximately

Examples of matching a stereo pair

left image

template, zoomed

right image

NCC image

NCC surface

SDD image

SDD surface

- Pattern from right image is searched in left image
 - NCC is normalised cross-correlation
 - SSD is sum of square differences

Numerical example of matching

- Matching of outlines yields sharper matches
 - interior matching: ratio perfect match/near miss is 1.5
 - outline matching: 2

Interior matching versus outline matching 2/2

ideal object

distorted object

- *dashed rectangle: template*
- *solid polygon: object*
- *circles: overlapping contour points*

- For **ideal** object, small shift of template results in
 - drastic decrease of contour overlap
 - negligible decrease of area overlap⇒ outline matching is sharper
- For **distorted** (or rotated) object,
 - outline overlap is small ⇒ likely to miss object
 - area overlap is large ⇒ likely to find object⇒ outline matching is less robust

Localisation accuracy versus robustness

- Contours matching
 - sharper matches: higher localisation accuracy
 - less robust: objects may be missed
 - faster
- Interior matching
 - less sharp matches
 - more robust
 - slower
- In general, one trades localisation accuracy for robustness
 - higher localisation accuracy \Rightarrow less robust

Critical issues in template matching

- Invariance to **changes in size and rotation**
- Robustness to **pattern distortion**
 - for example, because of varying viewing angle
- Robustness to **'noisy' matches**
 - unexpected patterns that produce high matching values
- **Computational load**

Handling variations in object size and orientation

- Image normalisation
 - transform image to **standard size and orientation**
 - assumes no size/orientation variation within image
 - requires definition of orientation
- Adaptive solutions
 - spatially **scale and rotate** template in each position
 - select best matching scale and rotation
 - very slow if number of scales and rotations is large
 - ⇒ used only for small number of scales and rotations
- Invariant solutions
 - use scale and rotation **invariant description**
 - compare descriptions instead of comparing patterns

Normalising image for size and orientation

template

original image

normalised image

- Letter **A** in top right corner differs in size and orientation
⇒ this letter *will not match*
- The other four letters will match
- How to define **image orientation**?

Outline

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 Template matching
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Fast implementation of matching

- Work with **local features** of images and templates rather than patterns themselves
 - edges, contours
 - useful for sparse and reliable features
 - may be sensitive to distortion (recall outline matching)
- For large templates ($> 13 \times 13$ pixels), implement cross-correlation via **Fast Fourier Transform (FFT)**

$$f \otimes w = \text{IFFT} \left[\text{FFT} [f(x, y)]^* \cdot \text{FFT} [w(x, y)] \right]$$

- *IFFT* is inverse FFT, X^* is complex conjugate of X
- FFT needs $O(N^2 \log N)$ operations for $N \times N$ image
- direct implementation needs $O(N^4)$ operations

Fast selection and rejection of candidates

- 1 Select match candidates, reject mismatches rapidly
 - 2 Carefully test selected candidates only
- Use coarse **grid of template positions**, rectify candidates
 - *coarse-to-fine* sampling for cross-correlation
 - works if peaks of cross-correlation has no spikes
 - Compute **simple properties** of template and image region
 - reject region if properties differ from template
 - Use **subtemplates**
 - reject candidate region if a subtemplate does not match
 - Set **threshold** on cumulative measure of mismatch
 - reject candidate when mismatch exceeds threshold

Outline

- 1 Matching and correspondence in computer vision
 - Correspondence in image analysis
 - Critical issues of matching
- 2 Template matching
 - Measures of dissimilarity between image and template
 - Measures of similarity between image and template
- 3 Robustness and localisation accuracy
- 4 Invariance, robustness and speed
 - Fast template matching
 - Consistency check for stable matching

Forward-backward matching

- Standard way to discard invalid matches
- Match is accepted if backward one is also valid

left image

right image

original ME

consistent ME

- Matching of stereo pair in presence of occlusion
 - ME is matching error: lighter pixel shows larger error
 - Consist. check removes wrong matches due to occlusion
